METHOD AND APPARATUS FOR MOULDING AND CURING A TYRE FOR
VEHICLE WHEELS

D e s c r i p t i o n

5

The present invention relates to a method and an apparatus for moulding and curing a tyre for vehicle wheels.

10 In a tyre production cycle it is provided that subsequently to a building process during which the different tyre components are manufactured and/or assembled, a moulding and curing process is carried out which aims at defining the tyre structure according to
15 a desired geometric configuration, usually having a particular tread pattern.

To this aim, the tyre is closed in a moulding cavity which is defined internally of a vulcanization mould
20 and shaped in accordance with the geometrical configuration of the outer tyre surfaces to be obtained.

A tyre generally comprises a carcass of toroidal ring-shaped conformation, including one or more carcass
25 plies braced with reinforcing cords lying in radial planes, i.e. containing the rotation axis of the tyre. Each carcass ply has its ends firmly associated with at least one annular reinforcing metal structure, usually
30 known as bead ring, which forms a reinforcement for the beads, i.e. the radially internal ends of said tyre having the function of enabling assembling of the tyre with a corresponding mounting rim. Disposed crownwise on said carcass is a band of elastomeric material
35 identified as tread band, in which at the end of the

- 2 -

- vulcanization and moulding steps a raised pattern is formed for ground-contact, which is adapted to ensure qualities of good traction ability, good output per kilometre, noiselessness and even wear resistance to
- 5 said tyre. A reinforcing structure usually known as belt structure is placed between the carcass and tread band. This belt structure in the case of tyres for cars usually comprises at least two radially superposed strips of rubberized material provided with usually
- 10 metallic reinforcing cords disposed parallel to each other in each strip and in crossed relationship with the cords of the adjacent strip, preferably symmetrically disposed with respect to the equatorial plane of the tyre. Preferably at a radially external
- 15 position said belt structure, at least on the ends of the underlying strips, also comprises a third layer of circumferentially-disposed (at 0 degrees) textile or metallic cords.
- 20 To the aims of the present description, it should be pointed out that by the term "elastomeric material" it is intended a composition comprising at least one elastomer polymer and at least one reinforcing filler. Preferably, this composition further comprises
- 25 additives such as cross-linking agents and/or plasticizers. Due to the presence of cross-linking agents, this material can be cross-linked by heating so as to form the final product.
- 30 There are moulding and curing methods in which a green tyre disposed on a rigid toroidal support is set within the mould. These methods are preferably used for tyres that, in accordance with recent building processes, are produced starting from a limited number of elementary
- 35 semifinished products fed to a toroidal support the

- 3 -

outer profile of which matches that of the radially internal surface of the tyre that is wished to be produced. Said toroidal support is moved, preferably by a robotized system, through a plurality of stations in each of which a particular tyre-building step is carried out, through automated sequences (see document EP 0 928 680 in the name of the same Applicant, for example).

10 The European Patent Application issued under No. 0 976 533 in the name of the same Applicant discloses a method and an apparatus for moulding and curing tyres for vehicle wheels in which a green tyre built on a toroidal support is closed in a vulcanization mould; subsequently steam or another fluid under pressure is fed into at least one fluid-diffusion gap created between the outer surface of the toroidal support and the inner surface of the tyre. In said application use of steam as the working fluid is specifically illustrated and described.

The Applicant has found that while use of steam as the working fluid is efficient for vulcanization, it has some drawbacks when it is brought into contact with the tyre.

In fact, during the starting step of the vulcanization process, hereinafter referred to as conformation step, steam by acting for a relatively long period of time (5-6 minutes, with a pressure of about 8 bars) in contact with the tyre being cured, may cause a partial slipping off of the carcass ply/plies from the bead region of the tyre.

35 This may reduce tensioning of the cords present in said

- 4 -

plies in the finished tyre thereby worsening tyre performance in terms of ride comfort and easy drive.

In tubeless tyres in addition, imperviousness to air or
5 air-tightness of the tyre under use conditions is obtained by a layer of elastomeric material identified as "liner", which layer during tyre building is the element directly in contact with said toroidal support.

10 It has been found that during vulcanization, the steam directly in contact with the inner tyre surface, i.e. said liner, can seep in creating small bubbles within the tyre itself.

15 In addition, said steam in contact with the toroidal support and the green tyre still cold, forms some condensate which generates a non-constant temperature range within the tyre itself.

20 The Applicant has also found that replacement of steam with a working fluid the critical temperature of which is lower than the vulcanization temperature does not enable a uniform vulcanization of the elastomeric material with which such a fluid comes into contact.

25

The Applicant has successfully experimented a vulcanization process (in particular of the type using a fluid directly in contact with the tyre) in which a fluid above its critical temperature is utilized in the
30 presence of a circulation of the fluid itself.

In a first aspect of the invention it is provided a method of moulding and curing a tyre for vehicle wheels comprising the following steps: building a green tyre
35 on a toroidal support having an outer surface the shape

- 5 -

of which substantially matches an inner surface of said green tyre; placing said green tyre supported by said toroidal support in a moulding cavity defined in a vulcanization mould, said moulding cavity having walls
5 conforming in shape to an outer surface of said tyre when vulcanization has been completed; pressing an outer surface of said green tyre against the walls of said moulding cavity by a working fluid under pressure flowing in at least one diffusion gap between said
10 outer surface of said toroidal support and said inner surface of said green tyre; heating said working fluid under pressure so as to supply heat to said green tyre in order to enable vulcanization thereof, said method being characterized in that said working fluid under
15 pressure in contact with said green tyre has a critical temperature lower than the vulcanization temperature and is submitted to circulation.

Since a fluid different from steam can be used due to
20 said circulation, the above described drawbacks are avoided in a direct manner: neither the liner and the rest of the tyre have bubbles at the inside thereof nor condensate is present during vulcanization. In addition, as better clarified in the following, the
25 step of conforming the tyre during vulcanization by means of a working fluid different from steam, only lasts few ten seconds. Consequently, the carcass ply does not tend to slip off the bead as depicted hereinabove and the characteristics of ride comfort and
30 easy drive are improved.

Finally, the above mentioned circulation enables tyres to be obtained that are cured in a uniform manner and show the planned features.

- 6 -

Preferably said method of moulding and curing a tyre for vehicle wheels, involves the step of supplying heat to said green tyre by heating of the mould.

- 5 In a preferred embodiment of said method in accordance with the invention a step of pre-heating said working fluid is provided.

10 In a further embodiment of the method in reference, said pre-heating step utilizes the heat for heating said mould by means of a heat exchanger.

In a particular embodiment of the method of the invention, said circulation is of the closed-circuit
15 type.

In a different embodiment of said method, said circulation is the open-circuit type.

- 20 In a different embodiment of the concerned method, said circulation step takes place by drawing said fluid off to the outside and restoring pressure through inflow of said fluid under pressure.

- 25 In another embodiment of said method, a step of recovering said fluid to use it again in a subsequent vulcanization operation is provided.

In a second aspect the invention relates to an
30 apparatus for moulding and curing a tyre for vehicle wheels comprising: a vulcanization mould arranged to receive a toroidal support adapted to support a green tyre within a moulding cavity; at least one passage device adapted to feed a working fluid under pressure
35 which is formed through the toroidal support and opens

- 7 -

onto the outer surface of said support, so as to press the outer surface of the green tyre against the walls of said moulding cavity; heating devices to transmit heat to said green tyre, characterized in that at least one circulation device for said working fluid under pressure is provided to enable circulation within said moulding cavity.

In a preferred embodiment, said heating devices comprise a plurality of ducts passed through by steam to heat the mould, a heat exchanger to transfer heat from said steam to said working fluid preheating it, and at least one series of electrical resistors to heat said working fluid to a predetermined temperature.

In a different embodiment, said heating devices comprise a plurality of ducts passed through by steam to heat the mould, at least one resistor to preheat said working fluid, and at least one series of electrical resistors to heat said working fluid to a predetermined temperature.

In a further embodiment of the apparatus in reference, said heating devices comprise a plurality of electrical resistors to heat said mould, at least one electrical resistor to preheat said working fluid, and at least one series of electrical resistors to heat said working fluid to a predetermined temperature.

In a different embodiment, said heating devices comprise a plurality of electrical resistors to heat said mould, a heat exchanger to preheat said working fluid and at least one series of electrical resistors to heat said working fluid to a predetermined temperature.

- 8 -

In another preferred embodiment of said apparatus, said circulation device comprises at least one forced ventilation system operatively associated with delivery/return ducts for said working fluid.

5

In a different embodiment, said circulation device comprises a recovery system for said working fluid comprising a recovery chamber and a compressor disposed in series, said recovery system being associated with
10 said forced ventilation system.

In another embodiment, said circulation device comprises a discharge valve, a compressor, a delivery valve and ducts associated therewith.

15

Further features and advantages of the invention will become more apparent from the detailed description of some preferred but not exclusive embodiments of a method and an apparatus for moulding and curing a tyre
20 for vehicle wheels in accordance with the present invention. This description will be set out hereinafter with reference to the accompanying drawings, given by way of non-limiting example, in which:

- Fig. 1 is a diagrammatic view partly in section
25 showing an apparatus for moulding and curing a tyre for vehicle wheels in accordance with the invention;

- Fig. 2 is a diagrammatic view partly in section showing an alternative embodiment of the apparatus in Fig. 1;

30 - Fig. 3 is a diagrammatic view partly in section showing an apparatus for moulding and curing a tyre for vehicle wheels in accordance with a further preferred embodiment;

- Fig. 4 is a diagrammatic view partly in section
35 showing an alternative embodiment of the apparatus in

Fig. 3.

With reference to Fig. 1, an apparatus for moulding and curing tyres for vehicle wheels in accordance with a first embodiment of the present invention is identified by reference numeral 101.

Apparatus 101 comprises a vulcanization mould 102 operatively associated with a vulcanization press 103, both only diagrammatically shown because they are made as disclosed in the mentioned document EP 0 976 533 in the name of the same Applicant, for example.

Mould 102 may consist of a lower mould half 102A and an upper mould half 102B, in engagement with a bed 103A and a closing portion 103B of press 103, respectively.

In the embodiment shown by way of example, each of the lower and upper halves 102A and 102B of mould 102 has lower 130A and upper 130B cheeks respectively and a lower sector crown 131A and an upper sector crown 131B, respectively.

The lower 102A and upper 102B halves are mutually movable between an open condition in which they are spaced apart from each other and a closed position shown in the figures in which they are disposed close to each other to form a moulding cavity 104 the inner walls of which defined by said cheeks and sectors reproduce the geometric conformation of the outer surface of a tyre to be obtained at the end of the moulding and vulcanization steps.

In more detail, the cheeks are designed to form the outer surfaces of the opposite tyre sidewalls, whereas

- 10 -

the sectors are intended to form the so-called tread band of the tyre itself, by creating a series of cuts and longitudinal and/or transverse grooves therein which are suitably disposed to form the desired "tread pattern".

Apparatus 101 further involves use of at least one toroidal support 10 of metallic or other solid material having an outer surface substantially reproducing the shape of an inner surface of the tyre. The toroidal support 10 conveniently consists of a collapsible drum i.e. made up of circumferential segments centripetally movable so as to take the toroidal support to pieces and enable easy removal of the tyre therefrom when working has been completed.

Apparatus 101 further involves heating devices preferably in the form of a plurality of ducts 105, 106, for passage of a heating fluid aiming at keeping mould 102 to temperature. The heating fluid employed in these ducts is preferably overheated steam that is preferably fed at a pressure included between 16 and 30 bars and at a temperature in the range of 170°C to 210°C.

Advantageously, other heating devices comprise a heat exchanger 107 disposed around the lower half 102A of mould 102 and preferably in the form of a pair of serpentine-shaped coaxial pipes 108 wound around said lower half. In particular, in the gap between the inner pipe and outer pipe, circulation of a steam flow is provided, whereas the inner pipe contemplates flowing of a working fluid intended for tyre moulding and vulcanization. This working fluid is preferably a fluid the critical temperature of which is lower than the

- 11 -

vulcanization temperature.

Advantageously, the steam flowing in the gap between said coaxial pipes is the same steam flowing in ducts 5 105, 106 intended for heating of mould 102, so that the same heat source is advantageously exploited for heating said mould 102 and for a preheating step of said working fluid.

10 As diagrammatically shown in the figures, apparatus 101 involves delivery ducts 109 and return ducts 110 for said working fluid which have a length close to mould 102 buried in a block 111 preferably made of a material having a high heat-exchange coefficient (bronze, for 15 example). Locally, around said delivery duct 109, provision is made for further heating devices buried in block 111 as well, preferably consisting of at least one series of electrical resistors 112. Said electrical resistors 112 are then operatively associated with at 20 least one thermocouple (not shown) to control the operating temperature of same (values included between 530°C and 700°C are provided). A second thermocouple (not shown) is preferably provided within mould 102 to check the operating temperature of the working fluid 25 (about 350°C-400°C).

Ducts 109, 110 are operatively associated with at least one passage device, by a connecting duct (not shown) for example, formed along at least one of the centring 30 spigots of said toroidal support 10, to enable diffusion of said working fluid under pressure within said toroidal support.

Said passage device involves appropriate branches 35 radially formed in the toroidal support 10 by which the

- 12 -

working fluid reaches an annular chamber provided internally of the toroidal support itself. Pressure generated by said fluid extends therefrom through a plurality of ducts opening onto the outer surface of the toroidal support 10, suitably distributed on the circumferential extension of same.

Pressure generated by the working fluid therefore reaches a diffusion gap created between the outer surface of the toroidal support 10 and the inner surface of the green tyre.

In a preferential embodiment, the diffusion gap is created in a direct manner following an expansion of the tyre caused by effect of a thrust action exerted by said working fluid under pressure.

In other words, tyre pressing against the walls of the moulding cavity 104 takes place concurrently with an expansion imposed to the tyre itself until bringing the outer surface thereof to completely adhere to the inner walls of the moulding cavity 104.

Said ducts 109, 110 of apparatus 101 are also connected to at least one device 120 for forced circulation of the working fluid and possible recovery of same between one vulcanization operation and the subsequent one. In particular the fluid-recovering operation becomes useful when fluid having an intrinsic cost of its own is selected as the working fluid.

Said device 120 as shown in Fig. 1 comprises a forced ventilation system 121 that may comprise fans, pumps or other means adapted to obtain circulation of the working fluid, a discharge valve 122 for possible

- 13 -

discharge of said fluid to the outside, in case of too much pressure for example, and a pair of valves 123, 124 of the return and delivery type respectively, to adjust return to a recovery system 125 and subsequent
5 delivery to mould 120 of the working fluid, respectively. More specifically, said recovery system 125 comprises a recovery chamber 126 operatively associated with a compressor 127 for restoration of the operating pressure (about 28-30 bars, for example). The
10 delivery valve 124 is connected to a duct 129 in turn associated with the inner one of the coaxial pipes 108, duct 129 coming out of said inner pipe being then connected to the forced ventilation system 121 to enable use of the working fluid at the end of the
15 preheating step.

In accordance with the method of the invention, the green tyre is disposed on the toroidal support 10 before the latter is inserted together with the tyre
20 itself, into the vulcanization mould 102 set in an open condition.

In particular, engagement of the tyre on the toroidal support 10 can be conveniently obtained by directly
25 building the tyre on the support itself. In this way the toroidal support 10 is advantageously utilized as a rigid shaped element for the purpose of forming and/or laying down the different components, such as carcass plies, reinforcing structures at the beads, belt
30 strips, sidewalls and tread band co-operating in forming the tyre. Further details as regards forming and/or laying down of the tyre components on the toroidal support 10 can be found for example in the European Patent Application issued under No. 0 929 680
35 in the name of the same Applicant.

- 14 -

Operation of apparatus 101, after placing said toroidal support 10 carrying the green tyre within the mould itself, involves closing of said mould 102 and
5 beginning of the moulding and vulcanization operations.

As already illustrated in document EP 0 976 533 in the name of the same Applicant, when the mould 102 is closed, the walls of the moulding cavity 104 keep some
10 distance away from the outer surface of the green tyre, particularly at the tread band thereof. During this step at all events, the tread band can be partly penetrated by the raised portions or projections arranged on the sectors to define said tread pattern.

15 When closure of mould 102 has been completed, the green tyre is submitted to a pressing step with its outer surface against the walls of the moulding cavity 104, concurrently with heat supply to cause molecular cross-
20 linking of the elastomeric material of which the tyre is made and consequent geometric and structural definition of the tyre itself.

To this aim, apparatus 101 is provided with the above
25 described passage device. Advantageously, the working fluid causing achievement of the desired pressure thereby enabling moulding of the tyre, also supplies the required heat for vulcanization.

30 In particular, assuming use of a gas such as nitrogen as the working fluid operating above its critical temperature, said gas is fed to mould 102 by opening of valve 124. The nitrogen gas under pressure that on coming out of valve 124 has a pressure of about 28 bars
35 and a temperature substantially corresponding to that

- 15 -

of the surrounding atmosphere, is advantageously sent through duct 129 to the heat exchanger 107 and by passage in the serpentine-shaped coaxial pipes 108 it carries out a preheating step until reaching a
5 temperature of about 80°C-100°C.

Duct 129 subsequently brings the nitrogen gas to the forced ventilation system 121 that admits it, through the delivery duct 109, to mould 102 and to the toroidal
10 support 10 carrying the green tyre. Close to mould 102 the resistors 112 buried in the block 111 perform the step of heating nitrogen bringing it to a temperature of about 350°C-400°C. Nitrogen subsequently reaches the gap present between the tyre and the toroidal support
15 starting the moulding and vulcanization step that has a duration of about 18-20 minutes.

At the end of the moulding and vulcanization step, before opening mould 102 to extract the tyre, re-
20 establishment of ambient pressure inside said mould is required and at the same time nitrogen recovery appears to be suitable since the latter has an intrinsic cost of itself. For the purpose the return valve 123 of the forced circulation device 120 is
25 opened and nitrogen is collected in the recovery chamber 126. Subsequently, after closing valve 123, a passage through compressor 127 restores an appropriate pressure value (about 28/30 bars), then said working fluid is again ready for a new moulding and
30 vulcanization cycle on opening of the delivery valve 124.

It will be appreciated that in the method of the invention a fluid operating above its critical
35 temperature (nitrogen in the example shown) is provided

- 16 -

as the working fluid generating the necessary pressure and temperature for moulding and vulcanization, which fluid has a lower thermal-exchange ability as compared with that of steam which is employed in the known art.

5

The Applicant has ascertained that advantageously the closed-circuit circulation imposed to said inert fluid by the forced ventilation system 121 enables the fluid to transfer heat to the tyre in a homogeneous manner, thus obtaining a finished product of uniform cross-linking without, among other things, the disadvantages due to use of steam.

In addition, during the first instants of the moulding step the tyre-conformation cycle can be carried out in a very short period of time (about 10-30 seconds) due to the operating pressure of the working fluid that can be imposed even to values as high as 28-30 bars. More specifically, as the fluid under pressure comes into contact with the green tyre by said gap which is formed between the outer surface of the toroidal support 10 and the inner surface of the green tyre, said tyre begins conforming according to the mould dies. Simultaneously, the cords of the plies present in the tyre and in particular those belonging to the carcass ply or plies are tensioned without tending to partly slip off the bead area and in particular the bead ring, thereby ensuring ride comfort and easy drive to the moulded and vulcanized tyre.

30

Without wishing to be bound to any interpretative theory, the Applicant thinks that in the short period of time during which the working fluid brings the tyre against the mould die to the moulding pressure, the blends due to their high viscosity retain the ply ends

35

- 17 -

in the bead region avoiding partial slipping off of same during the conformation step. The cords of the plies under these conditions grow longer; therefore they are submitted to tensioning enabling the above
5 stated features to be obtained in the finished tyre. Finally, the Applicant has observed that since the plies do not tend to slip off, also the blends forming the bead region stay in the correct position thereby ensuring sizes and structure in accordance with the
10 design.

In an alternative solution, the working fluid can be air. In this case, as shown in Fig. 2, the whole device 120 for fluid circulation is preferably reduced to
15 compressor 127, delivery valve 124, duct 129 and discharge valve 122, all of them connected with each other in series, so that an open-circuit circulation is obtained that at all events, as in the preceding example, surely enables the working fluid to transfer
20 heat to the tyre in a homogeneous manner, so that a finished product cross-linked in a uniform manner is obtained.

In this case air movement is carried out by drawing off
25 the air present in the return duct 110 through the discharge valve 122, and then restoring the operating pressure by admitting air to duct 129 through the delivery valve 124, and subsequently to mould 102 through the delivery duct 109.

30

The reduced complexity of device 120 for fluid circulation is due to the fact that air, unlike a fluid such as nitrogen, has a substantially negligible cost and therefore can be discharged in the surrounding
35 atmosphere.

- 18 -

In an alternative variant of the previously-described preferred embodiments of apparatus 101, the heat exchanger 107 can be replaced by one or more electrical resistors 128 placed downstream of compressor 127. In this case the preheating temperature (about 80°C-100°C) is reached downstream of said resistor 128, and the fluid coming out of the delivery valve 124 is directly admitted to the delivery duct 109 by the circulation device 120. The fluid-preheating step in this case is therefore performed by said resistor 128.

In a different embodiment, an apparatus 201 for moulding and vulcanization of vehicle tyres in accordance with the invention shown in Figs. 3, 4 contemplates the presence, unlike apparatus 101, of a plurality of electrical resistors 205 for the purpose of keeping the mould 102 to temperature during said moulding and vulcanization process.

In addition, said step of preheating the working fluid is preferably carried out downstream of compressor 127 by one or more resistors 128 that can also be replaced by a plate-type heat exchanger. In this way, irrespective of the working fluid employed or the type of circulation carried out, i.e. a circulation of the closed-circuit type or of the open-circuit type, said working fluid is directly sent to said delivery duct 109 on opening of the delivery valve 124.

It will be understood that in this different embodiment of apparatus 201 in accordance with the invention, the heating devices are preferably electric, whereas the moulding and vulcanization process is substantially identical with the previously described process.

- 19 -

C L A I M S

1. A method of moulding and curing a tyre for vehicle wheels comprising the following steps: building a green
5 tyre on a toroidal support (10) having an outer surface the shape of which substantially matches that of an inner surface of said green tyre; placing said green tyre carried by said toroidal support (10) into a moulding cavity (104) defined in a vulcanization mould
10 (102), said moulding cavity (104) having walls conforming in shape to an outer surface of said tyre when vulcanization has been completed; pressing an outer surface of said green tyre against the walls of said moulding cavity (104) by means of a working fluid
15 under pressure flowing in at least one diffusion gap between said outer surface of said toroidal support (10) and said inner surface of said green tyre; heating said working fluid under pressure so as to supply heat to said green tyre in order to enable vulcanization of
20 same, characterized in that said working fluid under pressure in contact with said green tyre has a critical temperature lower than the vulcanization temperature and is submitted to circulation.
- 25 2. A method of moulding and curing a tyre for vehicle wheels as claimed in claim 1, wherein the step of supplying heat to said green tyre by heating of said mould (102) is provided.
- 30 3. A method of moulding and curing a tyre for vehicle wheels as claimed in claim 1, wherein a step of pre-heating said working fluid is provided.
4. A method of moulding and curing a tyre for vehicle
35 wheels as claimed in claim 3, wherein said pre-heating

- 20 -

step utilizes the heat for heating said mould (102) by means of a heat exchanger (107).

5 5. A method of moulding and curing a tyre for vehicle wheels as claimed in claim 1, wherein said circulation is of the closed-circuit type.

6. A method of moulding and curing a tyre for vehicle wheels as claimed in claim 1, wherein said circulation
10 is of the open-circuit type.

7. A method of moulding and curing a tyre for vehicle wheels as claimed in claim 6, wherein said circulation step takes place by drawing said fluid off to the
15 outside and restoring pressure through inflow of said fluid under pressure.

8. A method of moulding and curing a tyre for vehicle wheels as claimed in claim 1, wherein a step of
20 recovering said fluid to use it again in a subsequent vulcanization operation is provided.

9. An apparatus for moulding and curing a tyre for vehicle wheels comprising: a vulcanization mould (102)
25 arranged to receive a toroidal support (10) adapted to support a green tyre within a moulding cavity (104); at least one passage device adapted to feed a working fluid under pressure, which is formed through the toroidal support (10) and opens onto the outer surface
30 of said support so as to press the outer surface of the green tyre against the walls of said moulding cavity (104); heating devices to transmit heat to said green tyre, characterized in that at least one circulation device (120) for said working fluid under pressure is
35 provided to enable circulation within said moulding

- 21 -

cavity.

10. An apparatus for moulding and curing a tyre for vehicle wheels as claimed in claim 9, wherein said
5 heating devices comprise a plurality of ducts (105, 106) passed through by steam to heat the mould (102), a heat exchanger (107) to transfer heat from said steam to said working fluid preheating it, and at least one series of electrical resistors (112) to heat said
10 working fluid to a predetermined temperature.

11. An apparatus for moulding and curing a tyre for vehicle wheels as claimed in claim 9, wherein said heating devices comprise a plurality of ducts (105,
15 106) passed through by steam to heat the mould (102), at least one resistor (128) to preheat said working fluid, and at least one series of electrical resistors (112) to heat said working fluid to a predetermined temperature.

20

12. An apparatus for moulding and curing a tyre for vehicle wheels as claimed in claim 9, wherein said heating devices comprise a plurality of electrical resistors (205) to heat said mould (102), at least one
25 electrical resistor (128) to preheat said working fluid, and at least one series of electrical resistors (112) to heat said working fluid to a predetermined temperature.

30 13. An apparatus for moulding and curing a tyre for vehicle wheels as claimed in claim 9, wherein said heating devices comprise a plurality of electrical resistors (205) to heat said mould (102), a heat exchanger to preheat said working fluid, and at least
35 one series of electrical resistors (112) to heat said

- 22 -

working fluid to a predetermined temperature.

14. An apparatus for moulding and curing a tyre for vehicle wheels as claimed in claim 9, wherein said
5 circulation device (120) comprises at least one forced ventilation system (121) operatively associated with delivery/return ducts (109, 110) for said working fluid.

10 15. An apparatus for moulding and curing a tyre for vehicle wheels as claimed in claim 14, wherein said circulation device (120) comprises a recovery system (125) for said working fluid comprising a recovery chamber (126) and a compressor (127) disposed in
15 series, said recovery system (125) being associated with said forced ventilation system (121).

16. An apparatus for moulding and curing a tyre for vehicle wheels as claimed in claim 9, wherein said
20 circulation device (120) comprises a discharge valve (122), a compressor (127), a delivery valve (124) and ducts (129) associated therewith.

(54) Title: METHOD AND APPARATUS FOR MOULDING AND CURING A TYRE FOR VEHICLE

(57) Abstract: It is disclosed a method and an apparatus for moulding and curing a tyre for vehicle wheels, said method comprising the steps of : building a green tyre on a toroidal support (10) having an outer surface the shape of which substantially matches that of an inter surface of said green tyre; placing said green tyre carried by said toroidal support (10) into a moulding cavity (104) defined in a vulcanization mould (102), said moulding cavity (104) having walls conforming in shape to an outer surface of said tyre when vulcanization has been completed; pressing an outer surface of said green tyre against the walls of said moulding cavity (104) by means of a working fluid under pressure flowing in at least one diffusion gap between said outer surface of said toroidal support (10) and said inner surface of said green tyre; heating said working fluid under pressure so as to supply heat to said green tyre in order to enable vulcanization of same, wherein said working fluid under pressure in contact with said green tyre is submitted to circulation.

INTERNATIONAL SEARCH REPORT

International Application No.

PCT/IB 02/01432

A. CLASSIFICATION OF SUBJECT MATTER
IPC 7 B29D30/06 B29C35/00

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 B29D B29C

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	EP 0 976 533 A (PIRELLI) 2 February 2000 (2000-02-02) cited in the application figures 1-3 column 8, line 49 - line 51 column 9, line 4-12 ---	1-3,9

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

* Special categories of cited documents:

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

T later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

X document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

Y document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/IB 02/01432

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this International application, as follows:

see additional sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☒ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. Claims: 1-8

Method of moulding and curing a tyre comprising the step of pre-heating the working fluid.

2. Claims: 9-16

Apparatus for moulding and curing a tyre, which is provided with:

- ducts passed through by steam to heat the mould,
- a heat exchanger to transfer heat from said steam to the working fluid and
- electrical resistors to heat said working fluid to a certain temperature.
